It is common to determine the direction of a magnetization in a magnetic wire by winding it on a drum and inspecting the wire by a magnetometer. In this method the magnetic wire wound on the drum forms several tracks, one next to the other, perpendicular to the axis of the drum. The tracks are defined by intersections of a zone (deviation) of the magnetic field perpendicular to the magnetization and a zone (wall) of the magnetic field parallel to the magnetization. An embodiment of such an apparatus is described in EP-A-0126995. It has become apparent, however, that this method of determination is somewhat disadvantageous. One disadvantage is that it takes more time than necessary to inspect a magnetic wire by a magnetometer.Multiple finger injuries and the effect of a finger splint. Twelve volunteers participated in this experiment to determine the effect of a splint that allowed independent movement of each finger during a 2 h impact task. The force of impact was 60 kp/sq cm on the middle finger. This created an equivalent force to that previously reported to cause injuries with direct pressure, although the splint would have no effect in patients who require a splint. Twelve subjects were tested wearing a modified orthotic splint (replacement of the thumb by a plastic rod, with the fingers freed to move freely). The average force required to produce each injury was significantly higher when wearing the splint (P less than 0.0001). Also, six subjects wearing the splint developed injuries to other fingers. The results support the need for orthotic devices in patients with
